KSBI-BIML 2024

Bioinformatics & Machine Learning(BIML) Workshop for Life and Medical Scientists

안녕하십니까?

한국생명정보학회가 개최하는 동계 교육 워크숍인 BIML-2024에 여러분을 초대합니다. 생명정보학 분야의 연구자들에게 최신 동향의 데이터 분석기술을 이론과 실습을 겸비해 전달하고자 도입한 전문 교육 프로그램인 BIML 워크숍은 2015년에 시작하여 올해로 벌써 10년 차를 맞이하게 되었습니다. BIML 워크숍은 국내 생명정보학 분야의 최초이자 최고 수준의 교육프로그램으로 크게 인공지능과 생명정보분석 두 개의 분야로 구성되어 있습니다. 올해 인공지능 분야에서는 최근 생명정보 분석에서도 응용이 확대되고 있는 다양한 인공지능 기반 자료모델링 기법들에 대한 현장 강의를 진행될 예정이며, 관련하여 심층학습을 이용한 단백질구조예측, 유전체분석, 신약개발에 대한 이론과 실습 강의를 함께 제공될 예정입니다. 또한 단일세포오믹스, 공간오믹스, 메타오믹스, 그리고 롱리드염기서열 자료 분석에 대한 현장 강의는 많은 연구자의 연구 수월성 확보에 큰 도움을 줄 것으로 기대하고 있습니다.

올해 BIML의 가장 큰 변화는 최근 연구 수요가 급증하고 있는 의료정보자료 분석에 대한 현장 강의를 추가하였다는 것입니다. 특히 의료정보자료 분석을 많이 수행하시는 의과학자 및 의료정보 연구자들께서 본 강좌를 통해 많은 도움을 받으실 수 있기를 기대하고 있습니다. 또한 다양한 생명정보학 분야에 대한 온라인 강좌 프로그램도 점차 증가하고 있는 생명정보 분석기술의 다양화에 발맞추기 위해 작년과 비교해 5강좌 이상을 신규로 추가했습니다. 올해는 무료 강좌 5개를 포함하여 35개 이상의 온라인 강좌가 개설되어 제공되며, 연구 주제에 따른 연관된 강좌 추천 및 강연료 할인 프로그램도 제공되며, 온라인을 통한 Q&A 세션도 마련될 예정입니다. BIML-2024는 국내 주요 연구 중심 대학의 전임 교원이자 각 분야 최고 전문가들의 강의로 구성되었기에 해당 분야의 기초부터 최신 연구 동향까지 포함하는 수준 높은 내용의 강의를 될 것이라 확신합니다.

BIML-2024을 준비하기까지 너무나 많은 수고를 해주신 운영위원회의 정성원, 우현구, 백대현, 김태민, 김준일, 김상우, 장혜식, 박종은 교수님과 KOBIC 이병욱 박사님께 커다란 감사를 드립니다. 마지막으로 부족한 시간에도 불구하고 강의 부탁을 흔쾌히 허락하시고 훌륭한 현장 강의와 온라인 강의를 준비하시는데 노고를 아끼지 않으신 모든 강사분들께 깊은 감사를 드립니다.

2024년 2월

한국생명정보학회장 이 인 석

Introduction to ConnectivityMap

ConnectivityMap 플랫폼은 3만 가지의 약물에 대한 300만 개 유전자 발현 프로파일을 포함하고 있어, 연구자들이 약물과 질병, 유전자 간의 복잡한 상호작용을 이해할 수 있게 도와주고 있다. 연구자들은 ConnectivityMap을 사용하여 기존 약물이 새로운 질병에 대해 어떤 효과를 보일 수 있는지 예측할 수 있으며, 이는 약물 개발 과정을 가속화하고 비용을 절감하는 데 큰 도움이 되고 있다.

ConnectivityMap 튜토리얼 강의를 통해 이러한 대규모 데이터셋을 탐색하고 분석하는 방법을 배우게 되며, 실제 사례 연구를 통해 ConnectivityMap이 어떻게 실제 연구에 적용될 수 있는지 배운다. 또한 이론적 지식뿐만 아니라 실제적인 적용 능력을 함양하는 것을 목표로 한다.

강의는 다음의 내용을 포함한다:

- ConnectivityMap 데이터의 이해
- ConnectivityMap 데이터의 활용
- ConnectivityMap 데이터의 응용

* 교육생준비물: 노트북 (메모리 8GB 이상, 디스크 여유공간 30GB 이상)

* 강의 난이도: 초급

* 강의: 전민지 교수 (고려대학교 의과대학)

Curriculum Vitae

Speaker Name: **Minji Jeon, Ph.D.**

► Personal Info

Name Minji Jeon
Title Assistant Professor
Affiliation Korea University

► Contact Information

Address 161, Jeongneung-ro, Seongbuk-gu, Seoul, 02708

Introduction to ConnectivityMap

고려대학교 의과대학 전민지

Genome-based Disease Research

- GWAS (Genome Wide Association Study)
 - To identify genomic variants that are statistically associated with a risk for a disease or a particular trait
 - Limitations: association with disease is generally not sufficient to establish causality or to provide mechanistic and circuit-level biological insights

Uffelmann, Emil, et al. *Nature Reviews Methods Primers* (2021)
Tam, Vivian, et al. *Nature Reviews Genetics* (2019)

ConnectivityMap Concept

- ConnectivityMap: Linking disease, therapeutics and cell physiology

The screenshot shows the Science journal article page. The title is "The Connectivity Map: Using Gene-Expression Signatures to Connect Small Molecules, Genes, and Disease". The authors listed are Justin Lamb, Emily D. Crawford, David Peck, Joshua W. Model, Rene C. Blat, Matthew A. Wrobel, Jim Lerner, Jean-Philippe Brunet, and Aravind Subramanian. The article is dated 29 Sep 2006. The abstract text reads: "To pursue a systematic approach to the discovery of functional connections among diseases, genetic perturbation, and drug action, we have created the first installment of a reference collection of gene-expression profiles from cultured human cells treated with bioactive small molecules, together with pattern-matching software to mine these data. We demonstrate that this 'Connectivity Map' resource can be used to find connections among small molecules sharing a mechanism of action, chemicals and physiological processes, and diseases and drugs. These results indicate the feasibility of the approach and suggest the value of a large-scale community Connectivity Map project."

Lamb, Justin, et al. *science* 2006 3

ConnectivityMap Concept

- Linking disease, therapeutics and cell physiology

4

ConnectivityMap Concept

- Gene expression data could be used for the functional annotation of small molecules and genes

5

Applications of the ConnectivityMap

- The Connectivity Map is a tool for the bench researcher

Nature Reviews | Cancer

Lamb, Justin. et al. *Nature reviews cancer* (2007)

6

Definitions

- Perturbation: an alteration of the function of a biological system, induced by external or internal mechanisms.
- Perturbagens: perturbing agents that are screened in an assay (e.g., small molecules, shRNA etc)
- Gene Signatures: differential expression of genes between two conditions, a control condition and a perturbation condition

7

ConnectivityMap v1

- Perturb cells and measure cellular responses

164 small molecules
FDA-approved drugs
nondrug bioactive tool compounds

4 cell lines
MCF7 (breast cancer)
PC3 (prostate cancer)
HL60 (leukemia)
SKMEL5 (melanoma)

564 microarray profiles
10 uM concentration
6 or 12 hours
with controls
-> **453 gene signatures**

8

ConnectivityMap v1

- Query
 - Input: gene signature (query signature)
 - Search: rank-based pattern matching strategy based on Kolmogorov-Smirnov statistics
 - The genes on the array are rank-ordered according to their differential expression relative to the control
 - The query signature is then compared to each rank-ordered list to determine whether up-regulated query genes tend to appear near the top of the list and down-regulated query genes near the bottom

9

Results: HDAC inhibitors

- Query gene signatures
 - 13 signatures downloaded from T24 (breast carcinoma) cells treated with Trichostatin A
- Results
 - New molecules: HC toxin, valproic acid

Fig. 2. HDAC Inhibitors. (A) HDAC inhibitors are highly ranked with an external HDAC inhibitor signature. The "bar-view" is constructed from 453 horizontal lines, each representing an individual treatment instance, ordered by their corresponding connectivity scores with the Glaser *et al.* (14) signature (+1, top; -1, bottom). All valproic acid ($n = 18$), trichostatin A ($n = 12$), vorinostat ($n = 2$), and HC toxin ($n = 1$) instances in the data set are colored in black. Colors applied to the remaining instances reflect the sign of their scores (green, positive; gray, null; red, negative). The rank, name [instance id], concentration, cell line, and connectivity score for each of the selected HDAC inhibitor instances is shown. Unabridged results from this query are provided as Result S1. **(B)** Chemical structures.

rank	perturbagen	dose	cell	score
1	vorinostat [1000]	10 μ M	MCF7	1
2	trichostatin A [873]	1 μ M	MCF7	0.969
3	trichostatin A [992]	100 nM	MCF7	0.931
4	trichostatin A [1050]	100 nM	MCF7	0.929
5	vorinostat [1058]	10 μ M	MCF7	0.917
6	trichostatin A [981]	1 μ M	MCF7	0.915
7	HC toxin [909]	100 nM	MCF7	0.914
8	trichostatin A [1112]	100 nM	MCF7	0.908
9	trichostatin A [1072]	1 μ M	MCF7	0.906
10	trichostatin A [1014]	1 μ M	MCF7	0.893
11	trichostatin A [332]	100 nM	MCF7	0.882
12	trichostatin A [331]	100 nM	MCF7	0.846
13	trichostatin A [448]	100 nM	PC3	0.788
14	valproic acid [345]	10 mM	MCF7	0.743
15	valproic acid [23]	1 mM	MCF7	0.735
16	valproic acid [1047]	1 mM	MCF7	0.733
17	trichostatin A [413]	100 nM	ssMCF7	0.725
18	valproic acid [410]	10 mM	HL60	0.725
19	valproic acid [458]	1 mM	PC3	0.680
33	valproic acid [409]	1 mM	HL60	0.634
39	valproic acid [1020]	500 μ M	MCF7	0.619
52	valproic acid [346]	2 mM	MCF7	0.582
61	valproic acid [1078]	500 μ M	MCF7	0.563
71	valproic acid [629]	1 mM	SKMEL5	0.539
72	valproic acid [347]	500 μ M	MCF7	0.539
73	valproic acid [989]	1 mM	MCF7	0.538
76	valproic acid [433]	1 mM	PC3	0.528
89	trichostatin A [364]	100 nM	HL60	0.507
92	valproic acid [497]	1 mM	ssMCF7	0.501
297	valproic acid [348]	50 μ M	MCF7	0
388	valproic acid [994]	200 μ M	MCF7	0
403	valproic acid [1002]	50 μ M	MCF7	0
419	valproic acid [1060]	50 μ M	MCF7	-0.537

10

Results

- anthelmintic drug parabendazole as an inducer of osteoclast differentiation (Brum et al., 2015)
- celastrol as a leptin sensitizer (Liu et al., 2015)
- compounds targeting COX2 and ADRA2A as potential diabetes treatments (Zhang et al., 2015)
- small molecules that mitigate skeletal muscular atrophy (Dyle et al., 2014) and spinal muscular atrophy (Farooq et al., 2009)
- new therapeutic hypotheses for the treatment of inflammatory bowel disease (Dudley et al., 2011) and cancer (Singh et al., 2016; Muthuswami et al., 2013; Wang et al., 2008; Schnell et al., 2015; Fortney et al., 2015; Wang et al., 2011; Churchman et al., 2015; Rosenbluth et al., 2008; Saito et al., 2009; Stockwell et al., 2012)

L1000 Assay Enables Massive Scale Up of Data

L1000 Assay Enables Massive Scale Up of Data

	L1000	RNA-Seq
Cost	\$	\$\$\$
Library prep?	Fast	Slow
Detection of non-abundant transcripts	No change	Needs deeper coverage
"Accuracy"	High	High
Evidence of additional benefit	?	

1M Profiles of CMap v2

A 25,200 unique perturbagens
 5,075 genes 314 biologics 19,811 small molecules

1.3 million profiles / 473,647 signatures

Perturbagen Type	pert_type designation in metadata files
Compound	trt_cp
Peptides and other biological agents (e.g. cytokine)	trt_lig
shRNA for loss of function (LoF) of gene	trt_sh
Consensus signature from shRNAs targeting the same gene	trt_sh.cgs
cDNA for overexpression of wild-type gene	trt_oe
cDNA for overexpression of mutated gene	trt_oe.mut
CRISPR for LLoF	trt_xpr
Controls - vehicle for compound treatment (e.g. DMSO)	ctl_vehicle
Controls - vector for genetic perturbation (e.g. empty vector, GFP)	ctl_vector
Controls - consensus signature from shRNAs that share a common seed sequence	trt_sh.css
Controls - consensus signature of vehicles	ctl_vehicle.cns
Controls - consensus signature of vectors	ctl_vector.cns
Controls - consensus signature of many untreated wells	ctl_untrt.cns
Controls - Untreated cells	ctl_untrt

1M Profiles of CMap v2

- small molecule compounds
 - ~1,300 FDA-approved drugs
 - ~5,585 bioactive tool compounds
 - 2000+ screening hits
- knocking-down genes (shRNA) or over-expressing genes
 - ~900 target/pathways of FDA-approved drugs
 - ~600 candidate disease genes
 - 500+ community nominations
- cells including primary cell lines, cancer cell lines, stem cell lines, and differentiated cell lines from different tissue types

Big Data Science with the BD2K-LINCS DCIC by Avi Ma'ayan

17

1M Profiles of CMap v2

- Control replicate
- Experiment replicate

- 384 wells in each plate
- About 18 control replicates per plate
- About 2~4 plates per batch
- About 366 experiments per batch

Big Data Science with the BD2K-LINCS DCIC by Avi Ma'ayan

18

Data Levels

Level 1 (LXB)	Raw fluorescent intensity (FI) values measured for every bead detected by Luminex scanners. Each 384-well plate generates 384 LXB files, where each file contains a fluorescent intensity value for each observed bead in the well.
Level 2 (GEX)	Gene expression levels for the 978 landmark genes, deconvoluted from the measured fluorescent intensity values.
Level 3 (NORM, INF)	NORM - Gene expression are normalized to invariant gene set curves and quantile normalized across each plate. INF- Additional values for 11,350 additional genes not directly measured in the L10000 assay are inferred based on the normalized values for the 978 landmark genes.
Level 4 (ZS)	Z-scores for each gene based on Level 3 with respect to the entire plate population. This comparison of profiles to their appropriate population control generates a list of differentially expressed genes.
Level 5 (MODZ)	replicate-collapsed z-score vectors based on Level 4. Replicate collapse generates one differential expression vector, which we term a signature . Connectivity analyses are performed on signatures.

19

ConnectivityMap Score

- Computing similarities - Weighted Connectivity Score (WTCS)

$$w_{q,r} = \begin{cases} (ES_{up} - ES_{down}) / 2, & \text{if } \text{sgn}(ES_{up}) \neq \text{sgn}(ES_{down}) \\ 0, & \text{otherwise} \end{cases}$$

Where ES_{up} is the enrichment of q_{up} in r and ES_{down} is the enrichment of q_{down} in r . $WTCS$ ranges between -1 and 1

- Normalization of Connectivity Scores (NCS)

- Given a vector of WTCS values w resulting from a query, we normalize the values within each cell line (c) and perturbation type (t) to obtain normalized connectivity scores (NCS) as

$$NCS_{c,t} = \begin{cases} w_{c,t} / \mu_{c,t}^+ & \text{if } \text{sgn}(w_{c,t}) > 0 \\ w_{c,t} / \mu_{c,t}^- & \text{otherwise} \end{cases}$$

20

ConnectivityMap Score

- Connectivity Map Score (Tau τ)
 - by comparing each observed NCS value $n_{cs_{q,r}}$ between the query q and a reference signature r to a distribution of NCS values representing the similarities between a reference compendium of queries (Q_{ref}) and r
 - Tau (τ) that ranges from -100 to $+100$ and represents the percentage of queries in Q_{ref} with a lower $|NCS|$ than $|n_{cs_{q,r}}|$

$$\tau_{q,r} = \text{sgn}(n_{cs_{q,r}}) \frac{100}{N} \sum_{i=1}^N [|n_{cs_{i,r}}| < |n_{cs_{q,r}}|]$$

21

Results

- Discovery of MOA of Unannotated Small Molecules

Figure 5. Characterizing Known and Unexpected Activities of Small Molecules

(A) HDAC inhibitor PCL substructure. Hierarchical clustering of pairwise connectivities of the HDAC inhibitor PCL members reveals substructure within the class. Pan-HDAC inhibitors cluster together, distinct from more isoform-selective compounds. (B) Antibacterials exhibit lower transcriptional activity than other drugs. Distributions of the maximum TAS per compound for 147 antibacterials and 2,372 known drugs in CMap-Touchstone (TS). The antibacterials' TAS distribution is significantly lower ($p < 3^{-11}$) than that of other drugs. (C) Comparison of unannotated compounds with known drugs. t-SNE projection of the signatures of 2,418 unannotated but transcriptionally active compounds (orange) with PCL members (teal). Some unannotated compounds occupy regions not covered by drugs, presenting opportunities for novel chemical development.

22

Results

- Discovery of a Selective CSNK1A1 inhibitor

Figure 6. Kinase Inhibitor Discovery Using Reference Transcriptional Signatures

(A) Discovery of ROCK1/ROCK2 inhibitor. Top left panel: chemical structure of BRD-2751, predicted to be a ROCK inhibitor. Right: TREEspot selectivity profile of Kinomesan binding assay confirmed compound binding to ROCK1/ROCK2. Bottom left: dose response testing by Kinomesan showed ROCK1 K_d of 56 nM.

(B) Discovery of novel CSNK1A1 inhibitor. Top left panel: the chemical structure of BRD-1868. Top right: TREEspot image of Kinomesan binding assay performed with BRD-1868 at 10 μ M demonstrated inhibition of 6/456 kinases tested, including CSNK1A1. Bottom left: CSNK1A1 binding by BRD-1868 confirmed by Kinomesan, with K_d 2.2 μ M. Bottom right: BRD-1868 inhibits phosphorylation of peptide substrate by CSNK1A1, with IC_{50} 12.9 μ M. Error bars indicate standard deviation between technical replicates.

Results

Table 4. An overview of the application of CMap for a number of different diseases

Disease	Method	Data set	Result	Drug	Reference
CNS injuries	CMap tool	Human MCF7 breast adenocarcinoma (GSE34331)	The findings show the hypothesis that inhibition of calmodulin signaling might allow neurons to alleviate substrate derived neurite growth restriction and CNS regeneration.	Calmodulin and piperazine phenothiazine (repurposed)	[54]
GBM	Pathway analysis and CMap tool	GBM data sets (GSE4290, GSE7696, GSE14805, GSE15824 and GSE16011)	Investigated antitumor drugs in GBM cell lines and identify novel drugs that can suppress GBM tumors.	Thioridazine	[55]
Gaucher disease (GD1)	Pathway analysis and CMap tool	GD1 mouse (GSE2308)	Predicted highly enriched anti-helminthic compounds for new drug action on GD1 and repurposing.	Albendazole and oxamniquine	[52]
Ovarian cancer	CMap tool	MCF7 and PC3 cell lines (GSE5258)	Found a compound as PI3K/AKT pathway inhibitor that shows the mechanism of cancer therapeutics.	Thioridazine	[56]
Stem cell leukemia (SCL)	GSEA and CMap tool	hESCs cell lines (GSE54508)	Found two HDAC inhibitors as potential inducers that can be used in treating SCL and acute megakaryoblastic leukemias.	Trichostatin A and suberoylanilide hydroxamic acid	[57]
T-cell acute lymphoblastic leukemia (T-ALL)	GSEA and CMap tool	Human and mouse T-ALL cell lines (GSE12948, GSE8416 and GSE14618)	Identified interconnecting regulatory pathways as therapeutic targets for T-ALL.	HDAC, PI3K and HSP90 inhibitors	[51]
Prostate cancer	CMap tool	Celastrol- and gedunin-treated cell lines (GSE5505 and GSE5508)	Identified target pathways of androgen receptor (AR) signaling and modulation of HSP90 MoA.	Celastrol and gedunin	[17]
Gastric cancer	Hierarchical clustering and CMap tool	Yonsei gastric cancer (GSE13861)	Predicted two possible drug candidates for gastric cancer therapy.	Vorinostat and trichostatin A	[53]
Myelomatosis	CMap tool	Human myeloma cell lines (GSE14011)	Found a drug with potential to induce suppression of cyclin D2 promoter regulation.	Fristimerin	[58]
AML	CMap tool	AML data (GSE7538)	Predicted novel treatment of human primary AML with parthenolide and transcriptional response of cells.	Celastrol	[59]

세포주 약물 반응 데이터의 활용

How to get gene signatures?

- The most fundamental problem:
 - Detecting and interpreting differences in the abundance of genes or other genomic features between experimental conditions, cell types, or disease states

	Wild-type		Mutant	
	Mouse 1	Mouse 2	Mouse 1	Mouse 2
Gene 1	45	60	30	39
Gene 2	0	4	3	7
Gene 3	1010	800	3099	3450
...

Differential expression analysis

- Differential expression analysis tests thousands of hypotheses (one test for each gene) for gene activity changes between conditions (case and control).
- Factors affecting analysis power include limited biological replicates, non-normal distribution of read counts, and measurement uncertainty for lowly expressed genes.

Differential expression analysis

- There are a number of software packages that have been developed for differential expression analysis of RNA-seq data
- Tools like edgeR and DESeq2 overcome these limitations using statistical models based on negative binomial distribution.
- There is no one method that performs optimally under all conditions

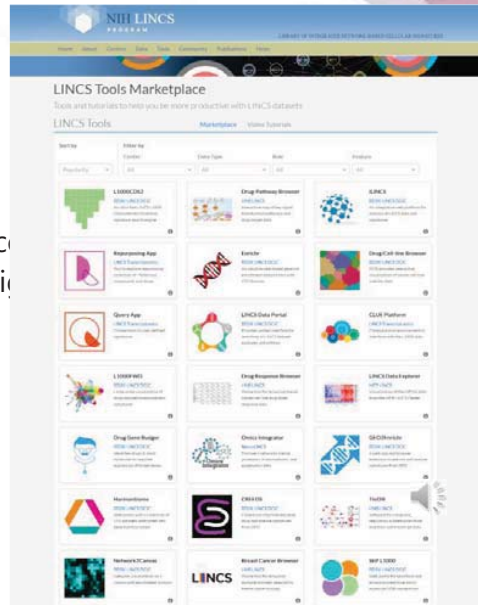

Soneson, Charlotte, and Mauro Delorenzi
BMC bioinformatics (2013)

ConnectivityMap

- Search tools

Tools

-  **Query**
Find perturbagens that give rise to similar (or opposing) expression signatures
-  **Touchstone**
Explore connectivities between signatures from ~3,000 drugs and genetic loss/gain of function of ~2,000 genes that make up the CMap touchstone (reference) database
-  **Data Library**
Explore datasets available through clue.io including L1000 cohorts and related perturbational information
-  **Repurposing**
Explore our collection of ~5000 drugs and tool compounds to find potential drug repurposing opportunities to improve disease treatments
-  **Morpheus**
Explore, analyze, and annotate heat maps. Choose an existing dataset or upload your own data (for example, gene expression or connectivity scores)
-  **Metadata Browser**
CLUE Metadata browser

ConnectivityMap

- Query signature
 - To find perturbagens that give rise to similar (or opposing) expression signatures
 - Take some time.. ~50min

Query

Query CMap for reference perturbagen signatures most similar (or dissimilar) to your samples.

Note that choosing 'Latest' from the query parameters section below, will run the query against our beta dataset released on (Dec 17, 2020)

1) Name your query
Please note that names must contain only alphanumeric characters. Any non-alphanumeric characters will be stripped.

test

2) Query parameters
Gene expression (L1000) Touchstone Individual query
Latest

3) Load a collection of Entrez Gene IDs from Listmaker for up-regulated gene sets (and optionally a collection for down-regulated gene sets). At any time you may choose an [GSE/DSSE](#) to fill in the boxes for the individual query.

UP-regulated genes [Load from my lists](#) Enter 15-150 genes for optimal results.

DOWN-regulated genes (optional) [Load from my lists](#) Please note that 150 is a max.

Invalid gene: not valid HGNC symbol or Ensembl ID, not used in query.
 Valid gene: valid HGNC symbol or Ensembl ID and part of BMS query, used in query.
 Valid but not used in query: valid HGNC symbol or Ensembl ID not part of BMS query, not used in query.
 More information can be found in this [Connectopedia](#) article.

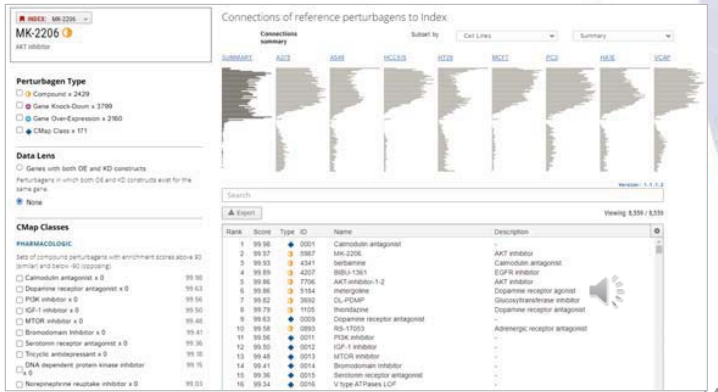

4) Review and submit. Only valid genes will be used in your query.

SigCom LINCS

- A cloud-agonistic platform for serving, storing, and que
 - >1 million signatures from
 - LINCS
 - GTEx (Genotype-Tissue Expression)
 - Signatures of aging
 - GEO (Gene Expression Omnibus)
 - RNA-seq signatures automatically extracted from GEO
 - CREEDS (Crowd Extracted Expression of Differential Signatures)
 - Participants extracted signatures from GEO

The diagram illustrates the SigCom LINCS workflow. It starts with multiple input sources: 'Any Search Term' (feeding into PubMed and Geneshot), 'Single Gene' (feeding into ARCHS4), and 'Reverse Search Appyters' (feeding into ARCHS4). PubMed and Geneshot feed into 'Enrichr', which then feeds into 'Gene Set'. ARCHS4 also feeds into 'Gene Set'. 'Gene Set' then feeds into 'SigCom LINCS Metadata Search'. The output of 'SigCom LINCS Metadata Search' is 'Up/Down Gene Sets'. Finally, 'Up/Down Gene Sets' feeds into 'SigCom LINCS', which produces 'Mimickers' and 'Reversers', resulting in '~1,000,000 Million Signatures'.

Title Modulating the transcriptional landscape of SARS-CoV-2 as an effective method for developing antiviral compounds
Organism Homo sapiens
Experiment type Expression profiling by high throughput sequencing
Summary The pandemic of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has imposed a significant burden on the human population. To understand the virus and the disease it causes we sought to interfere with the transcriptional response of the infected host. Utilizing the expression pattern of SARS-CoV-2-infected cells, we identified a region in gene expression space that was unique to virus infection and inversely proportional to the transcriptional footprint of known compounds characterized in the Library of Integrated Network-based Cellular Signatures (LINCS). Here we demonstrate the successful identification of compounds that display efficacy in blocking SARS-CoV-2 replication based on their ability to counteract the virus-induced transcriptional landscape. These compounds were found to potentially reduce viral load despite having no impact on viral entry or modulation of the host antiviral response in the absence of virus. RNA-Seq profiling implicated the induction of the cholesterol biosynthesis pathway as the underlying mechanism of inhibition and suggested that targeting this aspect of host biology may significantly reduce SARS-CoV-2 viral load.

3D PCA plot for samples

Figure 1. 3D UMAP plot for samples using 2500 genes having largest variance. The figure displays an interactive, three-dimensional scatter plot of the data. Each point represents an RNA-seq sample. Samples with similar gene expression profiles are closer in the three-dimensional space. If provided, sample groups are indicated using different colors, allowing for easier interpretation of the results.

URL: https://appyters.maayanlab.cloud/#/Bulk_RNA_seq

Figure 2. Clustered heatmap plot. The figure contains an interactive heatmap displaying gene expression for each sample in the RNA-seq dataset. Every row of the heatmap represents a gene, every column represents a sample, and every cell displays normalized gene expression values. The heatmap additionally features color bars beside each column which represent prior knowledge of each sample, such as the tissue of origin or experimental treatment.

Traditional Drug Discovery Pipeline: Ligand-based Drug Discovery

Introduction

- Ligand-based drug discovery
 - To find common structures among prototype drugs that bind to a desired target
 - To design structural analogs of the prototype drugs, and evaluate them

- **Target discovery** is essential
- Unable to work for **undruggable targets**
- **Limited range of drug candidates**: excludes drug candidates that may have similar effects despite binding to another protein

Developed a drug discovery model that can find functional analogs

https://application.wiley-vch.de/books/sample/3527312579_c01.pdf

Gene Expression-based Drug Discovery

- ConnectivityMap (CMap) by LINCS Consortium
 - Gene expression profile-based drug repurposing platform
 - Over 3 million gene expression profiles before and after drug treatments, shRNA knockdown, CRISPR knockout, etc. and 1 million gene signatures
 - User's up- and down-regulated genes in the signature DB to find chemical compounds/shRNA/CRISPR that can mimic or reverse them
 - Provide transcriptional response-based similarity scores of compound pairs (CMap Scores)
- However, as a drug repurposing platform, it is difficult to discover novel drug candidates

Approach

Bioinformatics, 2019

Results

Example pairs with similar structures but low actual CMap scores

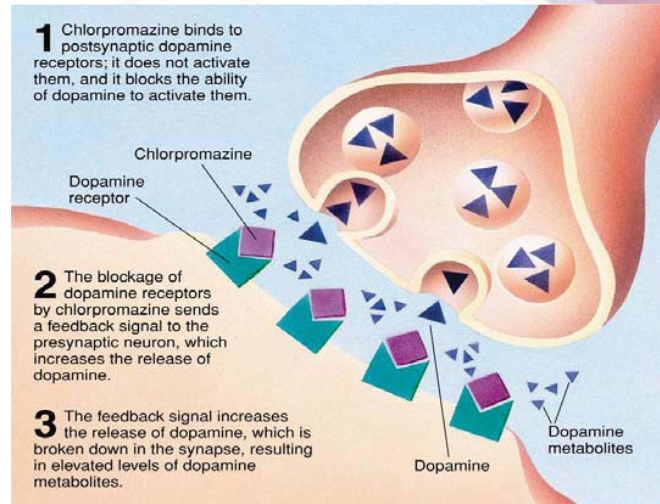

Example pairs with dissimilar structures but high actual CMap scores

Bioinformatics, 2019

Transforming L1000 profiles to RNA-seq-like profiles with deep learning

Minji Jeon^{1,2}, Zhuorui Xie¹, John E. Evangelista¹, Megan L. Wojciechowicz¹, Daniel J. B. Clarke¹ and Avi Ma'ayan^{1*}

Abstract

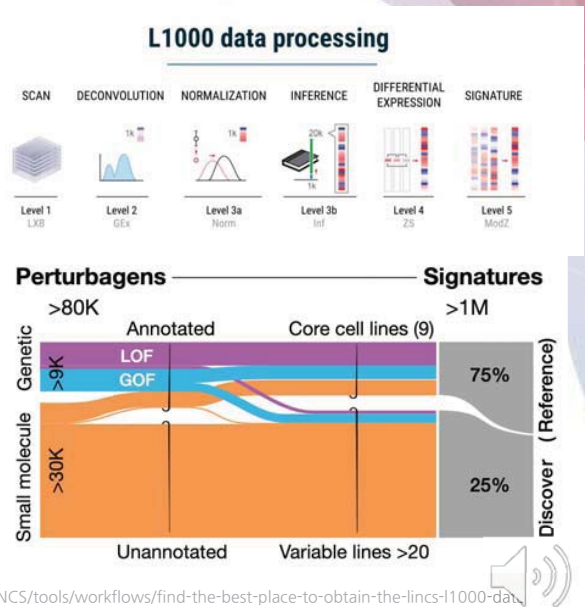

The L1000 technology, a cost-effective high-throughput transcriptomics technology, has been applied to profile a collection of human cell lines for their gene expression response to > 30,000 chemical and genetic perturbations. In total, there are currently over 3 million available L1000 profiles. Such a dataset is invaluable for the discovery of drug and target candidates and for inferring mechanisms of action for small molecules. The L1000 assay only measures the mRNA expression of 978 landmark genes while 11,350 additional genes are computationally reliably inferred. The lack of full genome coverage limits knowledge discovery for half of the human protein coding genes, and the potential for integration with other transcriptomics profiling data. Here we present a Deep Learning two-step model that transforms L1000 profiles to RNA-seq-like profiles. The input to the model are the measured 978 landmark genes while the output is a vector of 23,614 RNA-seq-like gene expression profiles. The model first transforms the landmark genes into RNA-seq-like 978 gene profiles using a modified CycleGAN model applied to unpaired data. The transformed 978 RNA-seq-like landmark genes are then extrapolated into the full genome space with a fully connected neural network model. The two-step model achieves 0.914 Pearson's correlation coefficients and 1.167 root mean square errors when tested on a published paired L1000/RNA-seq dataset produced by the LINCS and GTEx programs. The processed RNA-seq-like profiles are made available for download, signature search, and gene centric reverse search with unique case studies.

Keywords: L1000, RNA-seq, Gene expression translation, Generative adversarial networks

Introduction – The LINCS L1000 Data

- L1000 assay
 - The L1000 assay only measures the mRNA expression
 - An additional 11,350 genes are computationally imputed
- L1000 data
 - An expression profile is generated from a single plate
 - Signatures (differentially expressed genes) are calculated

Introduction – Limitations & Challenges

Limitations of the L1000 Data

- Half of the protein-coding genes are missing from the L1000 data
 - This limits knowledge discovery about those missing genes
 - This limits the potential for integration of the CMap data with other transcriptomics profiling data

Project Challenges

- Transform L1000 profiles to RNA-seq-like profiles at the full genome scale with Deep Learning
 - How can we train a model when there are not a lot paired L1000 and RNA-seq profiles for training?
 - How can we demonstrate that predicted RNA-seq-like profiles contain knowledge?
 - What new applications the predicted RNA-seq-like profiles can provide and how we can demonstrate these applications as use cases?
 - How the trained model compares to other published models and simpler baseline models?

De novo generation of hit-like molecules from gene expression signatures using artificial intelligence

Oscar Méndez-Lucio^{1,2*}, Benoit Baillif¹, Djork-Arné Clevert³, David Rouquié^{1,5*} & Joerg Wichard^{4,5*}

Finding new molecules with a desired biological activity is an extremely difficult task. In this context, artificial intelligence and generative models have been used for molecular de novo design and compound optimization. Herein, we report a generative model that bridges systems biology and molecular design, conditioning a generative adversarial network with transcriptomic data. By doing so, we can automatically design molecules that have a high probability to induce a desired transcriptomic profile. As long as the gene expression signature of the desired state is provided, this model is able to design active-like molecules for desired targets without any previous target annotation of the training compounds. Molecules designed by this model are more similar to active compounds than the ones identified by similarity of gene expression signatures. Overall, this method represents an alternative approach to bridge chemistry and biology in the long and difficult road of drug discovery.

Fig. 1 Graphical representation of the models and pipeline used in the study. Molecules were encoded using a model that transforms the canonical SMILES of a molecule into a latent representation that can be later decoded into the set of grammar production rules needed to reconstruct the original SMILES (a). The generative adversarial network in b has a Stage I where the generator (G_0 in blue) takes the desired gene expression signature together with a vector of random noise to produce a molecular representation that can be decoded into SMILES using the decoder (in red). The discriminator (D_0 in purple) calculates the probability of the molecular representation to be a real molecule and the conditional network (f_0 in green) calculates the probability of the molecular representation to match the gene expression signature. In Stage II, the generator (G_1 in blue) takes as input the desired gene expression signature together with a molecular representation (e.g., the one produced by G_0) to repeat the process. The general pipeline is represented in c where the generative adversarial network is trained with ~20 K compounds from the L1000 dataset²⁵ (see Methods for details) to be able to generate compounds from a desired gene expression signature during the prediction phase.

Fig. 3 Molecules generated from target knock-out gene expression signatures. a Distribution of similarity between all generated molecules and their closest active nearest neighbor using MACCS, Fraggle and Morgan Fingerprints for Stage I in blue and Stage II in green. b Chemical structures of some generated molecules and their closest active nearest neighbor for each of the ten different targets.

Abstract

Motivation: Identifying mechanism of actions (MoA) of novel compounds is crucial in drug discovery. Careful understanding of MoA can avoid potential side effects of drug candidates. Efforts have been made to identify MoA using the transcriptomic signatures induced by compounds. However, these approaches fail to reveal MoAs in the absence of actual compound signatures.

Results: We present MoAble, which predicts MoAs without requiring compound signatures. We train a deep learning-based coembedding model to map compound signatures and compound structure into the same embedding space. The model generates low-dimensional compound signature representation from the compound structures. To predict MoAs, pathway enrichment analysis is performed based on the connectivity between embedding vectors of compounds and those of genetic perturbation. Results show that MoAble is comparable to the methods that use actual compound signatures. We demonstrate that MoAble can be used to reveal MoAs of novel compounds without measuring compound signatures with the same prediction accuracy as that with measuring them.

Availability and implementation: MoAble is available at <https://github.com/dmis-lab/moable>

DeepSide: A Deep Learning Approach for Drug Side Effect Prediction

Onur Can Uner¹, Halil Ibrahim Kuru¹, R. Gokberk Cinbis¹, Ozgur Tastan¹, and A. Ercument Cicek¹

Abstract—Drug failures due to unforeseen adverse effects at clinical trials pose health risks for the participants and lead to substantial financial losses. Side effect prediction algorithms have the potential to guide the drug design process. LINCS L1000 dataset provides a vast resource of cell line gene expression data perturbed by different drugs and creates a knowledge base for context specific features. The state-of-the-art approach that aims at using context specific information relies on only the high-quality experiments in LINCS L1000 and discards a large portion of the experiments. In this study, our goal is to boost the prediction performance by utilizing this data to its full extent. We experiment with 5 deep learning architectures. We find that a multi-modal architecture produces the best predictive performance among multi-layer perceptron-based architectures when drug chemical structure (CS), and the full set of drug perturbed gene expression profiles (GEX) are used as modalities. Overall, we observe that the CS is more informative than the GEX. A convolutional neural network-based model that uses only SMILES string representation of the drugs achieves the best results and provides 13.0% macro-AUC and 3.1% micro-AUC improvements over the state-of-the-art. We also show that the model is able to predict side effect-drug pairs that are reported in the literature but was missing in the ground truth side effect dataset. DeepSide is available at <http://github.com/OnurUner/DeepSide>.

A Drug-induced Liver Injury Prediction Model using Transcriptional Response Data with Graph Neural Network

Doyeong Hwang^{*‡}, Minji Jeon^{*‡}, Jaewoo Kang^{*†§}

^{*}Department of Computer Science and Engineering

[§]Corresponding author

Abstract—Drug-Induced Liver Injury (DILI) is a major cause of failed drug candidates in clinical trials and withdrawal of approved drugs from the market. Therefore, machine learning-based DILI prediction can be key in increasing the success rate of drug discovery because drug candidates that are predicted to potentially induce liver injury can be rejected before clinical trials. However, existing DILI prediction models mainly focus on the chemical structures of drugs. Since we cannot determine whether a drug will cause liver injury based solely on its structure, DILI prediction based on the transcriptional effect of a drug on a cell is necessary.

Several machine learning models trained on datasets such as Liver Toxicity Knowledge Base (LTKB) [4] and Open TG-GATEs [5] were previously proposed for DILI prediction. Most of the previously proposed machine learning models are trained on drug structure information for predicting DILI [6]–[9]. However, such models used for DILI prediction do not consider genetic information or the structures and complex biological mechanisms of drugs [10]. Therefore, these models cannot predict whether a drug will cause liver injury based solely on its structure.

Fig. 1. The overall architecture of GLIT. The structure of a drug, the drug-induced gene expression level, and the dosage and duration of drug administration are used as inputs for GLIT. A drug embedding vector is extracted from the last layer of a neural network with three layers, and a drug-induced gene expression embedding vector is extracted from a graph neural network using a biological knowledge graph called OmniPath. The two embedding vectors are concatenated with the dosage and duration of drug administration information, and fed to the prediction layers of GLIT to predict DILI.

DeSIDE-DDI: interpretable prediction of drug-drug interactions using drug-induced gene expressions

Eunyoung Kim and Hojung Nam

Abstract

Adverse drug-drug interaction (DDI) is a major concern to polypharmacy due to its unexpected adverse side effects and must be identified at an early stage of drug discovery and development. Many computational methods have been proposed for this purpose, but most require specific types of information, or they have less concern in interpretation on underlying genes. We propose a deep learning-based framework for DDI prediction with drug-induced gene expression signatures so that the model can provide the expression level of interpretability for DDIs. The model engineers dynamic drug features using a gating mechanism that mimics the co-administration effects by imposing attention to genes. Also, each side-effect is projected into a latent space through translating embedding. As a result, the model achieved an AUC of 0.889 and an AUPR of 0.915 in unseen interaction prediction, which is competitively very accurate and outperforms other state-of-the-art methods. Furthermore, it can predict potential DDIs with new compounds not used in training. In conclusion, using drug-induced gene expression signatures followed by gating and translating embedding can increase DDI prediction accuracy while providing model interpretability. The source code is available on GitHub (<https://github.com/GIST-CSBL/DeSIDE-DDI>).

Predicting Cellular Responses to Novel Drug Perturbations at a Single-Cell Resolution

Leon Hetzel^{*1,3}, Simon Böhm^{*3}, Niki Kilbertus^{2,4},
Stephan Günemann², Mohammad Lotfollahi^{1,5}, and Fabian Theis^{1,3}

⁵ Wellcome Sanger Institute, Cambridge

Abstract

Single-cell transcriptomics enabled the study of cellular heterogeneity in response to perturbations at the resolution of individual cells. However, scaling high-throughput screens (HTSs) to measure cellular responses for many drugs remains a challenge due to technical limitations and, more importantly, the cost of such multiplexed experiments. Thus, transferring information from routinely performed bulk RNA HTS is required to enrich single-cell data meaningfully. We introduce chemCPA, a new encoder-decoder architecture to study the perturbational effects of unseen drugs. We combine the model with an architecture surgery for transfer learning and demonstrate how training on existing bulk RNA HTS datasets can improve generalisation performance. Better generalisation reduces the need for extensive and costly screens at single-cell resolution. We envision that our proposed method will facilitate more efficient experiment designs through its ability to generate in-silico hypotheses, ultimately accelerating drug discovery.

84

(1) Encoder-Decoder: (2) Attribute embeddings: (3) Adversarial classifiers:

Figure 1: Architecture of chemCPA. The model consists of three parts: (1) the encoder-decoder architecture, (2) the attribute embeddings, and (3) the adversarial classifiers. The molecule encoder G can be any graph- or language-based model as long as it generates fixed-sized embeddings h_{drug} . The MLPs S and M are trained to map the embeddings to the perturbational latent space. There, z_d is added to the basal state z_i and the covariate embedding z_{c_i} . In this work, the latter always corresponds to cell lines. The basal state $z_i = E_\theta(x_i)$ is trained to be invariant through adversarial classifiers A_ϕ^j and the decoder D_ψ gives rise to the Gaussian likelihood $\mathcal{N}(x_i | \mu_i, \sigma_i)$.

Table 1: Comparison of multiple models on their performance on generalisation to unseen drug-covariate combinations for dosage values of $1 \mu\text{M}$ and $10 \mu\text{M}$.

Introduction to ConnectivityMap

고려대학교 의과대학 전민지

DESeq2

- Models estimate parameters (mean and dispersion) to describe count data distribution accurately.
- Dispersion parameter α affects variance; edgeR and DESeq2 employ similar empirical Bayes methods to shrink α towards similar-gene dispersions, enhancing differential expression test results.
- DESeq2 workflow:
 - Normalize read counts by computing size factors, addressing differences in library sizes and library compositions.
 - Calculate dispersion estimate for each gene.
 - Plot dispersion estimates of genes against mean normalized counts, and fit a line.
 - Shrink dispersion values of each gene towards the fitted line.
 - A Generalized Linear Model accounts for confounding variables and negative binomial distribution, fitting count data.
 - For a contrast (e.g., drug-A treated vs. untreated), differential expression test assesses log fold change of normalized gene counts.
 - P-values are adjusted for multiple testing.

DESeq2: Normalization

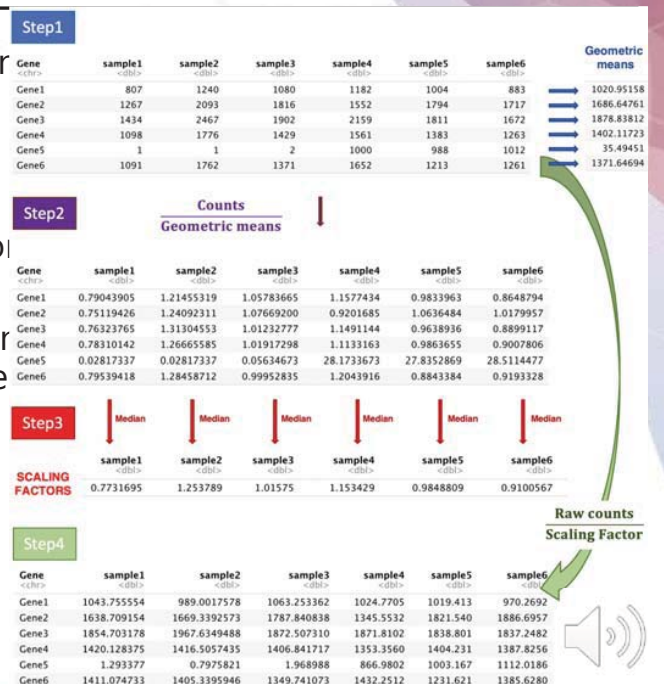

- DESeq2 expects as an input a matrix of raw counts (un-normalized counts).
- These counts are supposed to reflect gene abundance (what we are interested in)
- But they are also dependent on other less interesting factors such as gene length, sequencing bias, sequencing depth, or library composition

DESeq2: Normalization

- Step 1: DESeq2 creates a pseudo-reference wise geometric mean (for each gene).
- Step 2: For every gene in every sample, ratios are calculated.
- Step 3: The median value of all ratios for each sample is calculated.
- Step 4: Normalized counts can be obtained in a given sample by dividing the raw counts by that sample's scaling factor.

$$\hat{s}_j = \text{median}_i \frac{k_{ij}}{\left(\prod_{v=1}^m k_{iv}\right)^{1/m}}$$

- Number of cases is large
- Probability of an event happening is low
- Selecting mRNA from a large number of mRNA read
- mean = variance

DESeq2: Count Modeling

- But RNA-seq data does not fit Poisson distribution
 - variance \neq mean
- Negative Binomial distribution
 - variance $>$ mean

$$K_{ij} \sim NB(\text{mean} = \mu_{ij}, \text{dispersion} = \alpha_i)$$

$$\text{VAR}(K_{ij}) = \mu_{ij} + \alpha_i \cdot \mu_{ij}^2$$

K_{ij} = count of gene i for sample j

DESeq2: Count Modeling

- Dispersion estimation
 - Dispersion: When comparing gene expression levels between groups, it is important to know also its within-group variability
 - RNA-seq experiments typically have only few replicates
 - It is difficult to estimate within-group variability
 - Solution: pool information across genes with are expressed at similar level
 - assumes that genes with similar average expression strength have similar dispersion

DESeq2: Generalized linear model

- Generalized linear model:

$$\log_2(q_{ij}) = \beta_0 + \beta_1 \cdot x_j + \epsilon$$

$$q_{ij} = \frac{\mu_{ij}}{\text{SizeFactor}_j}$$

β_0 is the log2 expression level in the reference (control samples)

β_1 is the log2FC between treated and control cells

$x_j = 0$ if sample j is the control sample

$x_j = 1$ if sample j is the treated sample

Characteristic Direction

- Characteristic Direction (Clark et al. 2014, BMC bioinformatics)
 - Genes do not function in isolation but as part of a complex network of interactions
 - This leads to significant correlations
 - Univariate approaches can miss some structure in the data
 - Multivariate approaches are sensitive to the curse of dimensionality

Characteristic Direction

- Linear discriminant analysis
 - Bayes rules for the classification probability
 - The contribution of each b can be interpreted as quantifying the relative contribution of each component to the total differential expression giving the significance of the corresponding gene

Normal vector = direction of characteristics in gene expression data

$$\sum_{i=1}^p b_i^2 \equiv 1$$

Linear classification boundary
